

Metasonic® Base – Tools for Administrators

Metasonic® Base is the administrative component of Metasonic® Suite. It provides the necessary infrastructure and ensures smooth operation with Metasonic® Suite for technical departments as well as management and the IT department.

Metasonic® Base consists of:

- **Usermanager:**

With User Manager, you can easily create users and group them together. These groups are then assigned to a process role and thus embedded in a process.

Naturally, you can also add users and group information from existing systems (LDAP/Active Directory).

It is also easy to implement single sign-on.

This assignment embeds processes in the organization.

- **Instancemanager:**

With Instance Manager, the Metasonic® Suite administrator can administer ongoing process instances. A process instance is a concrete, ongoing process based on a process model.

Using Instance Manager, it is possible to:

- suspend ongoing process instances.
- assign tasks to new users.
- reset processes to a particular point.

- **Modelmanager:**

Model Manager deploys processes and related business objects. Deployment is the "uploading" of process models and business object definitions to the Metasonic server. Processes can be released or blocked during uploading. If a process is blocked, it can no longer be started in the workflow. Existing process instances continue to run. Processes can be released both for the Metasonic® Proof validation environment and the Metasonic® Flow workflow component. Metasonic® Flow also includes integrated version management. Model Manager can be used to administer existing versions of a process model individually and link them together if necessary. This allows multiple versions of a subprocess to be actively used in different process models.

- **Sysinfo:**

Integrated system information (sysinfo) displays all versions of the components being used in Metasonic® Suite for the administrator.
